TITLE: Chronicle (Khronika)

PERIODICAL: Geodeziya i kartografiya, 1958, Nr 6, pp. 77-78 (USSR)

ABSTRACT: From April 25 - 28, 1958 a Conference of the Chief Engineers and Directors of the Technical Control of Aerial Surveying Enterprises took place at the Moscow Central Bureau of Surveying and Cartography of the Ministry of the Interior of the USSR (Glavnoye upravleniye geodezii i kartografii MVD SSSR). It dealt with the improvement of the production organization and the quality of topographical work in surveying of official importance. The following lectures were held: S. G. Sudakov, Deputy Director of the Glavnoye upravleniye geodezii i kartografii MVD SSSR on: "Main Problems in the Further Improvement of Topographical Work in Surveying of Official Importance". The Chief-Engineers of the enterprises held the following lectures: S. G. Gavrilov - "Technical Projecting of Topographical-Geodesic Field Work". S. I. Yurov - "Comprehensive Performance of the Position- and Elevation Orientation of Aerial Photographs", B. D. Zaprudnov - "Taking a Combined Photograph of Flat Country Covered With Forests", L. A.

Card 1/3

graphic-Geodesic Production of the GUCK in 1957". A. P. Shcheglov - "Analysis of the Measuring Accuracy in the Triangulation of 2nd and 3rd order in the Years 1956-1957". B. V. Troitskiy - "Marking Control Points for the Geodesic Preparation of Photographs". I. V. Krylov - "Analytical Method for the Determination of Position- and Altitude Traverse Stations".

Based on the lectures it could be found that during the last years the topographic photographs of the scale 1:25 000 and 1:10 000 have undergone great development.

The conference decided to invite the representatives of the aerial surveying enterprises of the departments of the State Geodesic Control as well as of the interested offices to a conference at the end of 1958 and to investigate the project for the plan of development of the geodesic tasks in 1959-1965.

Razvedochnaya i promyslovaya geofizika, vyp. 26 (Exploration and Industrial Geophysics, Nr 26) Moscow, Gostoptekhizdat, 1958. 87 p. (Series: Obmen proizvodstvennym opytom) 4,000 copies printed.

Ed.: M.K. Polshkov; Exec. Ed.: Ye.G. Pershina; Tech. Ed.: A.S. Folosina.

PURPOSE: This booklet is intended for exploration geophysicists and geologists.

COVERAGE: This collection of articles includes discussions of improvements in seismic exploration techniques and interpretations of data obtained by the refracted and reflected waves method of seismic exploration. Individual articles discuss: the construction of gravimetric maps, improvements in industrial borehole equipment, the standardization of radioactive electro-logging equipment, and methods for computing labor productivity in geophysical operations. A nomogram to facilitate the interpretation of data and conditions when using gamma logging of boreholes is described. References accompany each article.

Title : Equivalent circuits for multiple-grid tubes

Periodical : Radiotekhnika, 10, 50-58, Mar 1955

Abstract : An equivalent linear circuit of a multi-grid vacuum tube, fully accounting for the plate and grid currents, is discussed in this article. The application of equivalent circuits to various problems are worked out on the following specific examples: determination of the stability conditions of mixer tubes and excitation of the transitron oscillators, also, on the example of phantastron performance during the slow process of capacitor charging, and the fast process of tripping. TITLE: Theoretical Determination of Parameters of a Coaxial-Waveguide Transition

PERIODICAL: "Izv. Leningr. elektrotekhn. in-ta", 1959, No. 39, pp. 3-19

TEXT: The authors consider a coaxial-waveguide transition in which the internal lead of the coaxial line serves as exciting element of the waveguide; its end either is free or closed to the broad wall of the waveguide. The method of calculating such a coaxial-waveguide transition is presented, and relations are derived which make it possible to determine its parameters and to analyze its design from the viewpoint of band width. The calculation is conducted on the following assumptions: 1. The characteristic impedance of the rod is assumed to be equal to that of a thin antenna in free space; 2. Fields on the rod surface are assumed to be equal to fields which would exist on the rod axis, if the rod were absent. With these presumptions, current distribution over the rod was found, and the problem of waveguide excitation by the rod was solved. Simple

3/058/61/000/003/024/021  
A001/A001

Theoretical Determination of Parameters of a Coaxial-Waveguide Transition

formulae were obtained to determine amplitude of waves excited in the waveguide, as well as input conductivities both from the side of the coaxial line and the side of the waveguide. The results of an experimental checking of the relations derived are presented. The results of theoretical calculations agree satisfactorily with experiments in case of non-resonance transition; in the case of resonance transition, the effect of the waveguide walls on the rod characteristic impedance should be taken into account. Examples of calculating coaxial-waveguide transitions are presented.

TITLE: Electromagnetic Waves Between Parallel Planes, When the Space Between Them is Partially filled With Ferrite<sup>25</sup>

PERIODICAL: Izv. Leningr. elektrotekhn. in-ta, 1959, No. 38, pp. 99-124

TEXT: As a result of solving an electrodynamic boundary-value problem, the propagation constants are determined in a waveguide of infinite height, i.e., in the space between two parallel metallic planes, which is filled with ferrite magnetized perpendicularly to the planes. Moreover, the reflection and transfer of waves is considered through a sudden discontinuity - the joint of two waveguides of different width, the first of which is filled with an isotropic dielectric and the second with magnetized ferrite. The cases are considered, when the wave coming from the first waveguide is a wave of electric or magnetic type. The infinite sums, appearing in the expression obtained for the conductance of the incident wave, are determined approximately from comparing the quasistatic and variational solutions for the capacitive and inductive diaphragms in the waveguide.

S/058/60/000/006/030/040  
A005/A001

Electromagnetic Waves Between Parallel Planes, When the Space Between Them is Partially Filled With Ferrite

For the special case, when the ground type wave can not propagate, an equivalent circuit is obtained, from which it follows that the electric and magnetic waves will transform into each other when reflected from the magnetized ferrite. This transformation is utilized in the ferrite-reflection transformer. The latter represents a short-circuited section of a waveguide with ferrite bar. Two rectangular waveguides are connected with this section through slots. The communication between them arises when the ferrite is magnetized.

TITLE: An Electronic Function Converter

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika, 1960, No.3, pp.376-385

TEXT: The problem of transforming a function can be formulated as follows. For a given electrical signal  $\xi$  and a known functional relationship

$$\alpha = f(\xi) \tag{1}$$

It is necessary to produce an electrical signal corresponding to the values  $\alpha = f(\xi)$ . The problem of transforming the given polar coordinates  $r, \varphi$  into rectangular coordinates  $x$  and  $y$  is often of great importance. Such a transformation is described by

$$x = r \cdot \cos 2\pi \frac{U_0}{U_{om}} \tag{2}$$

$$y = r \cdot \sin 2\pi \frac{U_0}{U_{om}}$$

Card 1/7

86796

S/142/60/000/003/011/017  
E192/E482

## An Electronic Function Converter

where  $\varphi = 2\pi U_0/U_{om}$ ; here  $U_0$  is a voltage and  $U_{om}$  is the value of the voltage corresponding to  $\varphi = 2\pi$ . The coordinate  $r$  is given by the voltage amplitude  $U_m$  which is a sinusoidal function of time. In order to obtain the voltage proportionate to the coordinate  $y$  of Eq.(2), it is possible to employ the circuit shown in Fig.1, where the voltage at the anode changes in accordance with

$$U_1(t) = E + U_m \sin \omega t$$

where  $E$  is a constant voltage component, while  $U_m$  is the amplitude of the variable component. The load of the tube in Fig.1 is in the form of an RC network connected in the cathode. The tube is normally closed by means of a biasing voltage applied between the grid and the cathode. At the instant  $t$ , a positive pulse having a duration  $\tau_u$  is applied to the grid and the tube becomes conducting during the presence of the pulse. Now, if the

Card 2/7

86796

S/142/60/000/003/011/017  
E192/E482

An Electronic Function Converter

time constant for charging the condenser  $C$  is much shorter than  $\tau_u$ ,  $C$  will be charged to the voltage almost equal to the anode potential. If  $RC \gg T$  ( $T$  is the period of the anode voltage) and the positive pulse at the grid is repeated periodically, the voltage across  $C$  changes insignificantly during the discharge period. The average voltage across  $C$  is therefore given by

$$U_c(t_1) = \gamma(E + U_m \cdot \sin \omega t_1) \quad (3)$$

where  $\gamma$  is a constant factor taking into account the influence of  $RC$  and  $T$ . In order to obtain the voltage proportional to the other coordinate ( $x$ ), a circuit, similar to that of Fig.1, is used but its anode voltage should be shifted in a phase by  $90^\circ$ . The positive pulses at the grid of this circuit should be applied at the same instants as those in a circuit of Fig.1. If the system is to operate correctly, it is necessary that the instant of the appearance of the positive pulse should be determined by the coordinate  $\varphi$ , that is by the voltage  $U_0$ . Consequently the  
Card 3/7

86796

S/142/60/000/003/011/017  
E192/E482

An Electronic Function Converter

following conditions should be met

$$t_1 = \frac{U_o}{U_{om}} \cdot T \quad (4)$$

In practice, this condition can be realised by means of the circuit shown in Fig.3 where the voltage  $U_{Bx}$  is in the form of a sawtooth waveform having the repetition period equal to a multiple of  $T$ . The amplitude of the sawtooth voltage should be equal to  $U_{om}$  or a multiple of it. As long as the sawtooth voltage is lower than  $U_o$ , the tube in Fig.3 is open and no current flows through the rectifier. However, at the instant when the sawtooth voltage becomes equal to  $U_o$  the tube becomes closed. A positive pulse is therefore obtained at the anode of the tube. This is differentiated and the resulting short pulse is applied to the grid of the tube in the circuit of Fig.1. Such pulses thus appear at the instant  $t_1$ . Fig.4 shows a practical circuit which can be used for the purpose of coordinate

Card 4/7

86796

E192/E482

### An Electronic Function Converter

transformation. Though the above case considers the transformation defined by Eq.(2), it can have very general application, since various non-linear functions which are periodical can be approximated by a Fourier series consisting of a number of harmonics. A block diagram of a device permitting the transformation of complex non-linear functions is given in Fig.5. Here the unit providing the constant component can be built in the form of an accurate divider of a highly stable voltage. The units for various harmonics are the form of the circuit shown in Fig.4. Each harmonic unit will produce a sinusoidal and co-sinusoidal voltage component. The generator of the sinusoidal oscillations for all the units can be the same, if a suitable number of frequency multipliers is employed. A converter circuit, of the type shown in Fig.4, was investigated experimentally. The circuit operated in the frequency of 15 kc/s and the duration of the positive pulse was 0.6  $\mu$  sec. The system was supplied from a stabilized force of 200 V. Curves illustrating the transformation of several functions by means of this device are shown in Fig.6.

Card 5/7

86796

S/142/60/000/003/011/017

E192/E482

## An Electronic Function Converter

The circuit of Fig.4 can be employed to perform various mathematical operations such as division, multiplication, root extraction, squaring and so on. The use of the circuit in determining the logarithm of a number is analysed in some detail. It is shown that in this case it is necessary to apply an exponentially rising voltage instead of a sawtooth voltage to the comparison circuit of Fig.3. The circuit can also be used for determining the number whose natural logarithm is known. The circuit has the following sources of errors: (1) instability of the voltage  $E$ ; (2) instability of the instant  $t_1$ , which may be due to the instability of the sawtooth voltage or the instability of the comparison circuit; (3) dependence of the coefficient  $\gamma$  of Eq.(3) on the internal resistance of the tube in the circuit of Fig.1 and (4) the instability of the voltage amplitude  $U_m$ . These errors are analysed in some detail and it is shown that the cathode follower in the converter circuit can be stabilized by using the system shown in Fig.7. There are 7 figures and 3 Soviet references.

TITLE:

Coupling of normal waves in waveguides with ferrites

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,  
Radiotekhnika, 1961, Vol.4, No.1, pp. 26-36

TEXT:

Separation of the variables in the Maxwell equations for waveguide containing ferrite requires that the directions of the coordinate axes be along the main axes of the ferrite permeability tensor and that the boundaries of the waveguide and of the ferrite coincide with the coordinate surfaces. This requirement limits the method to a narrow class of problems. The difficulty can be avoided by considering the ferrite permeability in the form of vector products independent of the coordinate system. To simplify the physical interpretation of the solutions, the field is resolved into a series of normal waves for a homogeneously-filled waveguide and their longitudinal components. Electromagnetic waves in waveguides of arbitrary cross-section, containing ferrite of arbitrary cross-section, magnetized in an arbitrary direction in the transverse plane, are represented as the sum of the empty waveguide waves and their longitudinal components. Expressions

Coupling of normal waves in .....

are obtained for the propagation constants and for the amplitudes of the waves. A new principle of transformation of an axially-symmetrical wave into a linearly-polarized wave by using ferrite is advanced and realized experimentally. The theory not only enables practical apparatus, at the present unamenable to calculation, to be analyzed, but also suggests new ferrite applications based on the mutual coupling of normal waves by the magnetized ferrite. One such application, a travelling wave switch, is described. The switch consists of circular waveguide and a transversely magnetized ferrite rod at its centre. At one end of the waveguide is a slot and the other end is terminated by a coaxial line. When the ferrite is magnetized, the wave passes without reflection from the slot into the coaxial line, but when the magnetic field is removed a decoupling of about 35 dB is obtained, as observed in the experimental, centimetric-wavelength model. The switch had the dimensions: diameter 9 mm, length 12 mm., and was filled with silicon-oil. The average power passed was 200 watts at 100 kw per pulse. Control was obtained by an electromagnet having 250 amp-turns. With little modification, the theory can be applied to travelling wave parametric amplifiers.

Coupling of normal waves in.....

The modified Maxwell equations are:

$$\text{rot } \vec{H} = j \omega \epsilon \vec{E} + \vec{j}, \quad \text{rot } \vec{H} = -j \omega \mu_0 \vec{H} - \vec{m} \quad (3)$$

where  $\vec{H}$  is the magnetic field vector;  $j = \sqrt{-1}$ ;  $\omega$  is the angular frequency;  $\vec{E}$  is the electric field vector;  $\vec{j}$  is the electric flux of polarization; and  $\mu_0$  is the permeability of homogeneous-filling. Eqs.(3) can be considered as comprising side currents, and using Lorentz' lemma in the form proposed by L.A. Vaynshteyn (Ref.7: "Electromagnetic waves", Izd-vo Sovetskoye radio, 1957) a solution can be obtained in the form of the sum of the normal waves and their longitudinal components, excited by the side currents in the waveguide with homogeneous filling. The normal waves of the transverse-magnetic and transverse-electric types, expressed for cylindrical waveguides, regular along the  $z$  axis, by the vector potentials, in the direction of the axis of the waveguide, are given in Appendix 1 as a system of vector functions which gives a physical picture of the field. In Appendix 2 are obtained formulae expressing the field ( $\vec{E}$  and  $\vec{H}$ ) in a waveguide with ferrite as the sum of the normal

TITLE: Metal-plate lens for circular polarization with covered zoning

SOURCE: Leningrad. Elektrotekhnicheskiy institut. Izv., no. 47, 1962, 56-62

TOPIC TAGS: metal plate lens, cellular lens, circular polarization, covered zoning, slotted thin ridge waveguide, crossed ridge waveguide, directivity pattern, principal lobe

ABSTRACT: A metal-plate microwave lens design proposed by E. K. Proctor (Trans. IRE on Antennas and Propagation, AP-6, M3, July 1958) is modified to permit circular polarization. The principal lobe of the directivity pattern of the antenna is of the order of  $6^\circ$  and the beam can be scanned within  $\pm 30^\circ$  by displacing the dipole over the focal plane of the lens. To match the antenna to the impedance of free space, each cell of the antenna is a rectangular waveguide loaded with crossed slotted thin ridges. The lens itself has a spherical external surface and an internal surface in the form of an ellipsoid of revolution.

Card 1/2

ACCESSION NR: AT4017554

the far focus of which coincides with the focus of the lens on the optical axis. The maximum lens diameter is 32.5 cm and the focal distance is 32 cm. The material is sheet brass 0.5 mm thick, and the finished lens weighs 2 kilograms. Tests of the antenna showed good agreement with the theoretical prediction.

TITLE: Application of the theory of a single conducting filament to the analysis of processes in cathode-ray devices

PERIODICAL: Izvestiya vysshikh shkolnykh zavedeniy, Radiotekhnika, v. 9, no. 1, 1967, 17 - 23

TEXT: The vector potential

$$A = \frac{1}{4\pi r} \int \frac{e^{-ikr}}{r} j dV \quad (1)$$

in the theory of a thin conducting filament (Pistol'kors, A.A. Antennы, Antennish, Svyaz'izdat, 1957; Shchelkunov, S. and Pruzhik, I. Antennы, teoriya i praktika, Antennas, Theory and Practice, Izd-vo Svyetskoye radio, 1951) is used for calculating the electric and magnetic fields produced by the filament;

Card 1/4

Application of ....

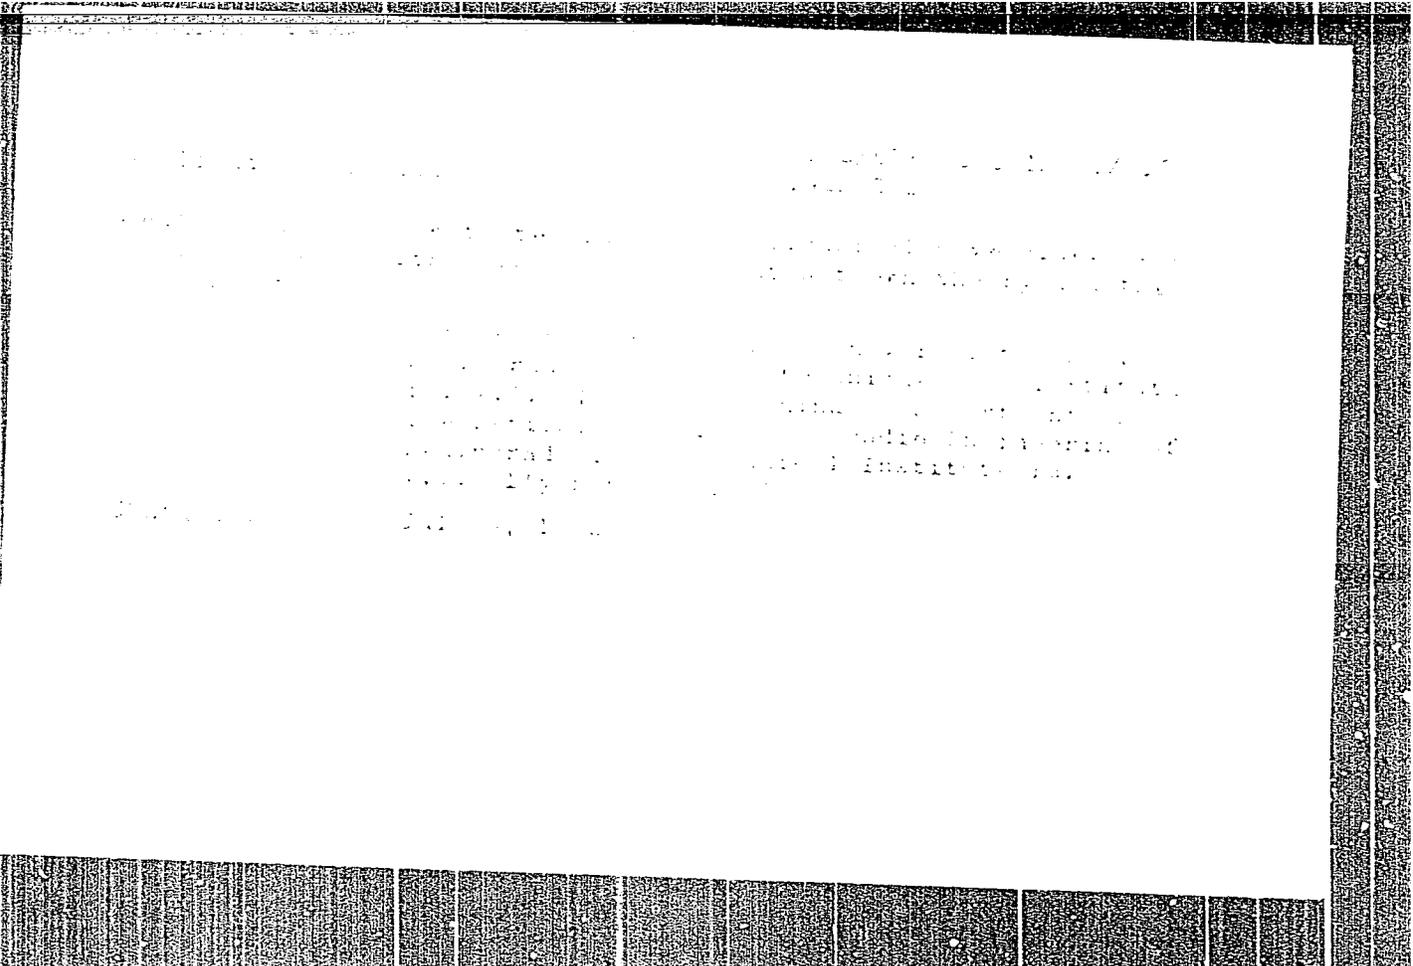

S/142/63/006/001/001/015  
E192/E382

$$\vec{E} = \frac{1}{i\omega\epsilon_0} (\text{grad div } \vec{A} - \Delta \vec{A}); \quad \vec{H} = \text{rot } \vec{A} \quad (2)$$

The vector potential depends on the current-density  $\vec{J}$  in the conductor. Eq. (2) gives only that portion of the field which is produced by the current flowing in the filament. It is therefore necessary to take into account the field produced by the currents flowing in the walls of a waveguide or other devices and add this to Eq. (2). This field would produce a current in the conductor which could be found by introducing an impedance parameter calculated by means of the skin-effect theory. Substitution of the current value into Eq. (1) leads to an integral equation with respect to  $\vec{A}$ .

... introducing an impedance parameter into Eq. (1) leads to an integral-differential equation with respect to the current in the conductor. However, in the theory of antennas it is usually sufficient to use an approximate differential equation where only the main portion of the integral in Eq. (1) remains; the sub-integral function in this tends to infinity for  $r \rightarrow 0$ . The current distribution found by using the approximate differential equation can be evaluated more accurately by the method of successive approximations.

TITLE: Increasing radiometer sensitivity by noise modulation of input signals

SOURCE: IVUZ. Radiotekhnika, v. 7, no. 3, 1964, 310-315

KEYWORDS: radiometer; periodic noise modulation; random noise modulation; gaussian noise; noise modulated radiometer; correlator; noise level reduction

ABSTRACT: Radiometer sensitivity may be increased by random-noise modulation (instead of periodic noise modulation) of its input signals and the subsequent insertion of a correlator based on the principle of a linear system with variable parameters (see Fig. 1 of the Enclosure). Both the random noise and reference noise are applied to the input. The changeover switch is controlled by the voltage of limited gaussian noise. The signal from the switch output and that corresponding to the set-noise of the receiver are amplified and applied jointly to the detector. In addition to the set-noise, volt-

Card 1/3

ACCESSION REF: AF4040847

are which varies in time with the random noise appears at the detector output. An g-f amplifier with properly selected frequency band is used to eliminate distortion of the effect signal. The correlator represents a linear system in which the conductivity of the detector varied in time with the modulating signal. The effective signal and the variation of system parameters are correlated between themselves but not with the set-noise. This results in an increase of constant voltage at the correlator output. Set-noise is transformed by the correlator in the widest band of a random form. This expansion of noise-spectrum density at the output according to the frequency is possible only with noise modulation of the input signal. The noise power level corresponding to one cycle with noise modulation is less than that with periodic modulation. This resulted in a reduction of the noise level at the radiometer output, which corresponds to the  $\sqrt{2}$  gain in the signal-to-noise ratio. Orig. art. has: 3 figures and 2 formulas.

TITLE: Transformation of transverse oscillations of an electron beam by short magnetic lenses

SOURCE: IVUZ. Radiotekhnika, v. 8, no. 5, 1965, 511-522

TOPIC TAGS: electron beam, electron beam tube

ABSTRACT: Vector-product eigen-vectors are introduced which split the equations of the motion of electrons in a magnetic field independently of the time and spatial conditions of the problem; the transformation of r-f waves by axisymmetrical magnetic lenses is represented in a simple mathematical form. Thus, a linearized equation of motion:  $(\vec{v}_0 \cdot \nabla) \vec{v} = \omega_c [\vec{v}, \vec{e}_z] - \frac{1}{2} \frac{\partial \omega_c}{\partial z} ([\vec{v}, \vec{r}] + [\vec{v}_0, \vec{s}] + [\vec{v}_0, \vec{r}])$ , (where  $\vec{v}_0$  is the undisturbed electron velocity before the lens,  $\vec{v}$  is the velocity increment due to the disturbance,  $\vec{s}$  is the electron displacement, and  $\omega_c = \frac{qH_z}{m}$  is the cyclotron-resonance frequency) can be split into these three scalar equations:

Card 1/2

UDC: 538.691

3  
B

L 39580-66

ACC NR: AP6000517

$$v_0 \frac{\partial^2 s_1}{\partial z^2} + i \omega_c \frac{\partial s_1}{\partial z} + \frac{l}{2} \frac{\partial \omega_c}{\partial z} s_1 = -l \frac{\partial \omega_c}{\partial z} \frac{x-y}{2};$$

$$v_0 \frac{\partial^2 s_2}{\partial z^2} - i \omega_c \frac{\partial s_2}{\partial z} - \frac{l}{2} \frac{\partial \omega_c}{\partial z} s_2 = l \frac{\partial \omega_c}{\partial z} \frac{x+y}{2};$$

$$v_0 \frac{\partial^2 s_2}{\partial z^2} + \frac{\partial \omega_c}{\partial z} \left[ (lx+y) \frac{\partial s_1}{\partial z} + (-lx+y) \frac{\partial s_2}{\partial z} \right] = 0.$$

It is proven that the levorotatory and dextrorotatory modes do not exchange their places; the transformation problem is reduced to solving a system of integral equations with the final results in a closed form. For short lenses, a matrix of

transformation of eigen-modes of the electron beam is introduced; the matrix clearly illustrates the process even on reversal of the permanent magnetic field. It is demonstrated that, upon a symmetrical magnetic-field reversal, cyclotron waves turn into synchronous and vice versa. The new formulas are offered for use in designing electron-beam tubes with transverse oscillations of electrons. Orig. art. has: 68 formulas.

TITLE: The action of various intravenously injected gasses on the organism

SOURCE: AN SSSR, Institut evolyutsionnoy fiziologii, Funktsii organizma v usloviyakh izmenennoy gazovoy sredy, v. 3, 1964, 53-59

TOPIC TAGS: intravenous gas injection, aeroembolism, decompression sickness

ABSTRACT: The authors studied the effects of intravenously injected oxygen, carbon dioxide, nitrogen, and helium on 50 cats and 18 rabbits. Fifteen chronic experiments were conducted on rabbits. Acute experiments took place under hexenal anesthesia. A kymograph was used to record respiration and blood pressure in the left femoral artery. A canule was introduced into the right femoral vein for the injection of gases, and the rate at which gas could be injected into the vein was accurately regulated. In a number of acute experiments, animals breathed pure oxygen or helium-oxygen mixtures when gas was injected. In such cases tracheotomies were conducted and respiration took place by means of a small valve which was con-

Card 1/3

L 42195-65

ACCESSION NR: AT5010598

ected to the tracheotomy tube. In 14 experiments a comparative analysis of the reaction of animals to the intravenous injection of gasses was conducted on animals with intact nervous systems and on animals with resected vagus nerves. In all, there were 15 carbon dioxide, 40 oxygen, 90 air, and 26 helium-oxygen-mixture injections. The rate at which gasses were injected depended upon the objective of the experiment. In chronic experiments, gasses were injected into the auricular vein of rabbits and their condition and behavior were then observed.

The experiments showed that changes in respiration and circulation produced by intravenous injection of various gasses were very close to changes in these functions observed during acute decompression disruptions. This indicated that aeroembolism of the venous system and lung vasculature play a dominant role in decompression disruptions. It was also found that different gasses, injected intravenously, differed in their physiological effect. The most acute physiological effect occurred when nitrogen was injected. In descending order, helium, oxygen, and carbon dioxide had less effect on the organism. This can be explained by the fact that the diffusion of the gasses administered differed and that oxygen and carbon dioxide were

Cont. 2/3

L 42195-65

ACCESSION NR: AT5010598

already chemically associated with the organism. The consequences of artificial aeroembolism in its most severe stage depend upon the diffusion correlation which occurs in the lungs between aeroembolisms and gaseous mixtures which accumulate in alveolar areas. In the elimination of aeroembolisms, the diffusion of gases from lung capillaries in the alveoli play a leading role. These facts should be considered when analyzing decompression disruptions or their treatment. The authors concluded that aeroembolism can serve as an experimental model for general decompression disruptions. Orig. art. has 4 figures.

E+1

TITLE: Experimental aereoembolism under conditions of hypo- and hyperthermia

SOURCE: AN SSSR. Institut evolyutsionnoy fiziologii, Funktsii organizma v usloviyakh izmenennoy gazovoy sredy, v. 3, 1964, 72-78

TOPIC TAGS: hypoxemia, aereoembolism, decompression sickness, central nervous system, hypothermia, hyperthermia

ABSTRACT: The purpose of the present investigation was to determine how temperature affected the resistance of the organism to the effects of aereoembolism. Experiments were conducted on rabbits weighing 1.9-4.0 kg. In all, 23 chronic and 13 acute experiments were conducted. In the chronic experiments the rabbits were injected in the auricular vein with 2 ml of air for 1 min. The animals were then freed and observations were conducted on their initial and final reactions to aereoembolism. Of 23 rabbits, 8 served as controls and did not undergo any thermal stress prior to injection of air, 8 were subjected to preliminary cooling, and 7 were exposed to preliminary heating. In the acute experiments, the control animals which

1 4213-03

contours of a rabbit. Water and ice were added between the two walls of the vat. When rectal temperature had reached 34.0—34.4° C (which took 1—2 hr in the chronic experiments), the animals were removed from the chamber and given injections of air. In the acute experiments the rabbits remained in the vat in a fixed position throughout the entire experiment. When the rectal temperature of these animals had reached 34° C, the cold water was replaced by water at 20—25° C. The aim of this regimen was to keep the temperature of the animals at a constant level. Heating of rabbits in both acute and chronic experiments was carried out by placing them in a special wooden hutch with a door and window. By means of seven electrodes located within the hutch, the temperature of the air was raised to and maintained at a level of 42—43° C. When the rectal temperature of the rabbits had reached 42° C, they were removed from the hutch and, in the chronic experiments, left as in the hyperthermia experiments. In the acute experiments, the animals were removed from the hutch when their rectal temperature reached 43.0° C and placed in the Nikolayev-Subbotin vat. When the temperature of animals in the vat began to drop, they were covered with hot water bottles. In all cases rectal temperature was measured by means of thermocouples and thermometers from the beginning of cooling through the end of the experiment.

Card 2/3

L 4:192-69

had been heated and cooled were placed in a fixed position without anesthesia. In this group arterial pressure and respiration were recorded kymographically. Cooling of the animals took place in a vat developed by Nikolayev and Subbotin—a double-walled metal vessel designed along the

The experiments revealed that when animals had been cooled or heated their resistance to experimental aeroembolism was increased. This increase in resistance to aeroembolism was more pronounced during hypothermia than during hyperthermia. The mechanisms of resistance to aeroembolism during hypothermia and hyperthermia are evidently different in nature. Resistance to aeroembolism is probably aided during hyperthermia by the quicker elimination of air bubbles from the blood stream and during hypothermia by a lowering of the sensitivity of the central nervous system to deleterious reflex influences associated with gas bubbles and hypoxemia.

TITLE: Comparative characteristics of the circulatory and respiratory reactions of anesthetized dogs to decompression and artificial aeroembolism

SOURCE: AN SSSR, Institut evolyutsionnoy fiziologii. Funktsii organizma v usloviyakh izmenennoy gazovoy sredy, v. 3, 1964, 79-86

TOPIC TAGS: aeroembolism, respiration, circulation, decompression sickness, bends

ABSTRACT: The first objective of the experiment was to study the respiratory and cardiovascular reactions of the organism to decompression and artificial aeroembolism in chronic experiments. The second objective was to elucidate whether training for artificial aeroembolism was effective in increasing the resistance of the organism to decompression disruption or, conversely, whether increasing the resistance of the organism to decompression increased its resistance to intravenous injection of gases. Experiments were performed on three dogs trained to lie on one side in a special cradle and breathe through a mask. An MPO-2 oscillograph was used to

REPORT NO: AT5010602

record respiration and pulse. At the same time, gas counters registered the volume of lung ventilation. All these indices were recorded following exposure to the compression from pressures of 4.5 atm (exposure 15-16 min), or to air embolus injection of air in quantities of 20-15 ml in the course of 1-1.5 min. Fig. 1 shows the system used to inject air into the experimental

The dogs were exposed to decompression, and when typical symptoms of bends occurred (paralysis of the rear limbs), the indices described previously were recorded for 3—5 min, the animals were then given therapeutic recompression. In all, 187 tests were conducted with decompression and 14 of them intravenously injected gasses.

Changes in respiration and cardiac activity of unanesthetized dogs during decompression and artificial aeroembolism were essentially similar. Training the organism for artificial aeroembolism increases the resistance to decompression disruptions, training for decompression disruptions increases the resistance of the organism to intravenous injections of gasses. Increasing the resistance of the organism to decompression in the first experiments is based primarily on conditioning the reaction of the respiratory and cardiovascular systems to aeroembolisms.

The authors feel that the reaction of the organism to decompression and artificial aeroembolism is conditioned by the fact that deleterious functional shifts are eliminated and protective functional shifts developed.

It is also suggested that these protective reactions develop more rapidly than gas bubbles form in the blood. Orig. art. has 7 figures.

TITLE: Neutron diffusion length and moderation length in diphenyl and monoisopropyl diphenyl

PERIODICAL: Referativnyy zhurnal, Fizika, no. 4, 1962, 61, abstract 4B461 (V sb. "Neytron. fizika". Moscow, Gosatomizdat, 1961, 192 - 197)

TEXT: The diffusion length of thermal neutrons was measured in diphenyl at  $t = 35^\circ, 85^\circ$  and  $130^\circ\text{C}$  and in monoisopropyl diphenyl at  $t = 20^\circ\text{C}$ . Deviation from operating temperature did not exceed  $\pm 2^\circ$ . The following values of  $L$  were obtained:  $4.77 \pm 0.14$  cm,  $4.93 \pm 0.08$  cm and  $5.47 \pm 0.04$  cm for diphenyl and  $3.34 \pm 0.31$  cm for monoisopropyl diphenyl. The mean value of the transport cross section of hydrogen in noncrystalline matter that was calculated on the basis of these data and reduced to  $t = 20^\circ\text{C}$  turned out to equal  $\sigma_{tr}^H = 35.7 \pm 1.2$  barn. The age of fission neutrons  $\tau_{fis}$  and of neutrons from a Po-Be source  $\tau_{sou}$  was also measured in solid diphenyl ( $t = 35^\circ\text{C}$ ) up to indium resonance. Measurements were carried out in a cylinder 40 cm in diameter and 90 cm in height placed in the thermal

Neutron diffusion length and...

column of a reactor, the source of fission neutrons being an enriched uranium target-converter. Control measurements with the Po-Be source, carried out at different experimental geometries and cylinder sizes, showed that the distribution of resonance neutrons in diphenyl surrounded by graphite corresponds to the distribution in an infinite medium. It was found that  $\tau_{fis} = 54.2 \pm 2.5 \text{ cm}^2$  and  $\tau_{sou} = 106.5 \pm 6.8 \text{ cm}^2$ . At the same time, measured values of neutron age appreciably exceed calculated values.

TITLE: New measurements of  $U^{235}$  fission neutron age in hydrogen-containing substances

PERIODICAL: Atomnaya energiya, v. 12, no. 2, 1962, 151 - 152

TEXT: The distributions of 1.46-ev neutrons as a result of slowing down  $U^{235}$  fission neutrons in  $H_2O$  and  $C_{15}H_{16}$  were measured for two source thicknesses: 0.3 and 1.8 mm. An indium detector was placed in a stainless-steel tank in the thermal column of the reactor for measuring the age of neutrons slowed down in  $C_{15}H_{16}$ . A highly enriched uranium metal target converting fast fission neutrons into thermal neutrons was the neutron source. The neutron distribution was determined by two targets, one at the end of a 150 mm long aluminum tube, the other 120 mm from the bottom of the tank for control measurements, which showed that the aluminum tube did not distort distribution. On the outside of the tank bottom another target was

Card 1/2

TITLE: Some results of pulse measurements of the diffusion parameters of organic liquids

PERIODICAL: Atomnaya energiya, v. 12, no. 4, 1962, 331-332

TEXT: A pulsed source was used to measure the decrease constant  $\alpha$  of thermal neutrons in  $C_{12}H_{10}$  (100-250°C) and  $C_{15}H_{16}$  (18-250°C). The measurements were carried out in a cylindrical tank with a Cd piston. The moderator above the piston served as an additional fast-neutron source. The geometrical parameter  $\Omega$  was varied by means of the piston.  
 $\alpha = 1/T + D\Omega - (c_D - c_T)\Omega^2$ ; T - life-time with respect to absorption, D - diffusion coefficient,  $c_D$  - coefficient of diffusion cooling,  $c_T$  - transport-theoretical correction; from  $D = \bar{\lambda}_{tr}\bar{v}_0/3$  which was obtained from the  $\alpha$ -measurements,  $\lambda_{tr}$  was calculated for each temperature, when

Some results of pulse ...

assuming the thermal neutron spectrum as being Maxwellian and the mean neutron velocity  $v_0 = \sqrt{2kT/m}$  (T - absolute temperature of the medium). From the curves  $\bar{\lambda}_{tr} = f(v_0)$ ,  $\bar{\lambda}_{tr} \sim v_0^{0.33 \pm 0.03}$  (diphenyl) and

$\bar{\lambda}_{tr} \sim v^{1.58 \pm 0.12}$  (monoisopropyl diphenyl) was obtained.  $\lambda_{tr}(v)$  also differs

considerably for equally structured media. For diphenyl the neutron spectrum was most similar to the Maxwellian. Nelkin's method was used to determine  $c_D$  when assuming weak dependence of  $\lambda_{tr}$  on the neutron energy ( $\bar{\lambda}_{tr} \sim E^\alpha$ ,  $\alpha$  is a free parameter):  $c_D = (\alpha + 1/2)^2 \sqrt{\pi} D^2 / v^0 M_2$ , where  $M_2$  is the second moment of neutron energy. The calculated values agree with the measured ones within the limits of error. There are 2 non-Soviet references. The reference to the English-language publication reads as follows: M. Nelkin. J. Nucl. Energy, 8, 48 (1958).

TITLE: Interaction of fast neutrons with uranium and thorium nuclei

PERIODICAL: Atomnaya energiya, v. 13, no. 1, 1962, 62-63

TEXT: A beam of reactor neutrons with energies between 3.5 and 13.5 Mev (in which the number of neutrons decreases linearly with increasing  $E_n$ ) was used to study the interaction of neutrons with U and Th nuclei. The beam passed along a steel-lined channel (25 mm wide) and through a paraffin shield to strike the U or Th target, a ball of 23 mm diameter. The scattered neutrons were recorded by НИКФИ-К (NIKFI-K) nuclear emulsion plates of 100  $\mu$  thickness. The experiment was carried out in three stages: first the scattered neutrons were recorded, then the target was removed and the background measured, finally the target was replaced by an emulsion plate and the spectrum of the reactor neutrons was measured. The resulting spectra  $\sigma(E_n)$  are stated numerically for the scattering angles 30, 45, 60, 90, 120, and 150° in the case of U and 30, 60, 90, 120 and 165° in that of

TITLE: The age of fission neutrons in water

SOURCE: Moscow. Inzh.-fiz. institut. Nekotoryye voprosy\* inzhenernoy fiziki (Some problems in engineering physics), no. 4, 1963, 43-46

TOPIC TAGS: nuclear reactor, neutron, fission neutron, neutron age, neutron absorption

ABSTRACT: The authors note that recent experiments to determine the age of neutrons in water indicate satisfactory agreement between the value of  $26.0 \pm 0.5$  cm<sup>2</sup> given by Kh. Gol'dshteyn, P. Tsveyfel and D. Foster (Trudy\* Vtoroy mezhdunarodnoy konferentsii po mirnomu ispol'zovaniyu atomnoy energii Ganeva, 1958). Izbr. dokl. inostrannykh uchenykh. T.2 - "Neytronnaya fizika". M., Atomizdat, 1959, str. 689) and the new values of  $27.3 \pm 1.0$  and  $27.3 \pm 0.9$  cm<sup>2</sup> given by L. N. Yurova, A. A. Polyakov, and A. A. Ignatov (Novyye izmereniya vozrasta neytronov v vode. "Atomnaya energiya", 10, no. 2, 1961) and by Lombard and Blanchard (Nucl. Sci. Engng, 7, 5, 1960), respectively. It is pointed out that the rated and experimental data converge, if the dependence of the spatial distribution of the

Card 1/3

ACCESSION NR: AT4018976

slowed neutrons on the effect of the absorption of these neutrons in the source is considered during the experiment. However, the last two papers mentioned contain no calculations confirming the existence of this dependence. In the present paper, an estimation of this effect is given on the basis of a concrete example. An infinite laminar source, with thickness  $d$ , is considered. The material of the source is U-235. The flow distribution from the right-hand side of the source ( $x \geq 0$ ) is found. All the neutrons are broken down into three energy groups and the assumption is introduced that the laminar source absolutely does not absorb neutrons with energy greater than 1234 ev. An expression for the spatial distribution of the stream is derived, after which the neutron age with different source thicknesses can be easily computed. For a plain (flat) case, when

$$\tau = \frac{1}{2} \cdot \frac{\int_0^{\infty} x^2 \phi(x) dx}{\int_0^{\infty} \phi(x) dx}$$

the following are the results:

when  $d = 0$   
 when  $d = 0.18$  cm

$\tau = 26.9$  cm<sup>2</sup>  
 $\tau = 31.8$  cm<sup>2</sup>

Card 2/3

ACCESSION NR: AT4018976

The authors note, in conclusion, that absorption of slowed neutrons in the source may have a substantial influence on the spatial distribution, with the latter, in turn, influencing the value of the neutron age in the medium. (fig. art. has: 12 formulas.)

TITLE: Non-elastic scattering of fast neutrons

SOURCE: Moscow. Inzh.-fiz. institut. Nekotory\*ye voprosy\* inzhenernoy fiziki (Some problems in engineering physics), no. 4, 1963, 59-90

TOPIC TAGS: neutron, neutron scattering, fast neutron, non-elastic scattering, magnesium target, nickel target, copper target, zirconium target, lead target, bismuth target

ABSTRACT: In the basic experiment, the results of which are described in this article, neutrons with an energy  $E_0 = 2.5$  Mev were obtained as the result of the reaction  $D(d, n)He^3$  with a mean energy of incident deuterons of approximately 170 kev. The tests were conducted on a plane almost perpendicular to the direction of the incident deuterons. The source spectrum consisted of the basic group of neutrons with energy of  $2.5 \pm 0.120$  Mev and neutrons with energy less than 2.0 Mev, caused by the background. To record the neutrons, nuclear photoplates type 4 and Ya-1-2105 obtained from the N.-1. kinofotoinstitut (Scientific Research Institute for Motion Picture Photography) were used with an emulsion layer 200 and 103 microns thick, respectively. In terms of their chemical composition,

Card 1/5

**ACCESSION NR: AT4018978**

these emulsions resemble the Ilford C-2 emulsion and in the 0.5 - 2.5 Mev energy region have the same decelerating ability. The geometry of the experiment is illustrated. Targets of the test materials were made in the form of truncated cones. The dimensions of these cones and other experimental data are tabulated. The neutron source, the target and the detector are so positioned as to record neutrons scattered at an angle of 100 - 150° (calculated mean scattering angle = 100°). In order to increase the scattering, two targets were used and a photo-plate dector was placed between them, with the emulsion-covered side of the plate coinciding with the direction of propagation of the neutrons. With this type of arrangement, the detector simultaneously records the scattered and the source neutrons. In order to record the background neutrons and the source neutrons, a second detector was positioned symmetrically with respect to the first. Thus, this geometrical arrangement made it possible, in a single experiment, to obtain the spectra and intensity of three different neutron streams (source neutrons, background neutrons and scattered neutrons) at the same time. The yield proton traces were measured on the plates in two directions: in the direction of the source neutron streams and in the direction of the background and scattered neutron streams. Measurements were made of the traces of all yield protons

Card 2/5

ACCESSION NR: AT4018978

located in the emulsion at an angle of not more than  $13^\circ$  to the stream of incident neutrons. In this experiment, the plates measuring the source neutron spectrum also served as monitors. The different measurements were compared on the basis of the intensity of the neutrons of the basic group of the source neutron spectrum (energy region 2.0 - 2.6 Mev), with the same intensity taken in the calculation of the scatter sections. The spectra of neutrons with a minimum energy of 0.8 Mev were considered. In the spectrum of the scattered neutrons, a number of maxima can be discerned, the position of which was determined with an accuracy of  $\pm 50$  kev. To each maximum seen in the spectrum of the unelastically scattered neutrons there corresponds a definite excitation energy of the forming nucleus. The derived values for these energies are given in a long table, which incorporates the results of previous studies as well. The various excitation levels and energy values are discussed in detail for each of the test materials (magnesium, nickel, copper, zirconium, lead and bismuth). In a further section of the article, a formula is given for calculating the cross section of elastic and non-elastic scattering of neutrons with an energy of 2.5 Mev and the results of such computations are given in a table. Two control experiments to check the results of the basic experiment are described, and the measurement of the spectra and section of neutrons with an energy of 2.5 Mev non-elastically scattered by lead nuclei at angles of  $0^\circ$  -  $40^\circ$  and  $100^\circ$  is considered. The values

Card 3/5

ACCESSION NR: AT4018978

derived in this work for the elastic scattering section are in good agreement with the results of other previously published work. This is also true of the energy values of the nuclear excitation levels. The cross section values for non-elastic neutron scattering with excitation of individual nuclear levels are, by and large, in satisfactory agreement with previous findings. All results confirm the presence of anisotropy in the angular distribution of non-elastically scattered neutrons with incident neutron energy on the order of 2.5 Mev. "The measurements of Ni were carried out by T. Ye. Petrova in 1954, those on Zr by G.V. Kotel'nikova in 1955." Orig. art. has: 5 tables and 11 figures.
